foreword

Manuel Hermenegildo
Director, IMDEA Software Institute
Quality research in technology-related areas is arguably the most successful and cost-effective way of generating knowledge, welfare, wealth, and sustainable growth, and this is perhaps more relevant today than ever. The Madrid Institute of Advanced Studies (IMDEA) was created by the Madrid Regional Government as a new institutional framework to foster social and economic growth through research of excellence and technology transfer in a number of strategic areas with high potential impact. Within this framework, in early 2006 a team of officials, scientists from Madrid universities, and representatives of leading Spanish companies worked together to lay the foundations and objectives of a research institute in the science and technology of software development—an area with a high potential for raising industrial competitiveness, creating value, and ultimately improving quality of life. A group of us were then asked in late 2006 to turn these plans into a reality, the IMDEA Software Institute within the IMDEA Network, contributing also to closing a historical gap, since, in contrast to other European countries, there are very few reference research centers in Computer Science in Spain.

Only every now and then is one offered the opportunity to be part of something that can truly make a difference. Full of hopes, enthusiasm, and determination, we set out to put in place an organization capable of attracting to Madrid top talent from all over the world to increase the quality, magnitude, and impact of research in the science and technology of software development in Spain. The Institute was born in early 2007, starting operations in temporary premises within the School of Computer Science of the Technical U. of Madrid (UPM), and the first new researchers arrived shortly thereafter. Looking back now, after gathering the material for this 2010 annual report, the progress towards the goals is encouraging.

Without a doubt, the main acquired strength of the IMDEA Software Institute is its people: its researchers and its support staff. The Institute now includes a total of 37 researchers (22 excluding PhD students and interns) from 14 different nationalities (Argentina, Belgium, Czech Republic, France, Germany, Mexico, India, Indonesia, Ireland, Macedonia, Spain, Sweden, Ukraine, and USA). They have joined the Institute after having worked at or obtained their Ph.D. degrees from 25 different prestigious universities and research centers in 11 different countries, including Stanford University, Carnegie Mellon U., or Microsoft Research in the USA, INRIA in France, U. of Cambridge in the UK, the Max Planck Software Institute in Germany, or ETH in Zurich, to name just a few. Also, 52 international researchers have visited and given talks at the Institute to date. During 2010 IMDEA Software Institute researchers have published 43 articles in top-level refereed conferences and journals (including the top venues in the field, such as POPL, PLDI, CAV, VMCAI, ESOP, SAS, ICLP, ICSE, CSF, CCS, CF, VSTTE, TCS, ACM TIST, TPLP, etc. and receiving a best student paper award), edited 5 proceedings of major conferences or workshops, given 9 invited talks, participated in 30 program committees of international conferences, and been members of 15 editorial boards of journals and steering committees of conferences.

Also, during this time IMDEA Software Institute researchers have participated in and secured funding from 9 major research projects, 4 of which are funded by the European Union, collaborating with a large number of companies in such projects, including currently Siemens, Atos, Fredhopper, BBVA-Globalnet, and Deimos, and, in recent projects, Telefonica, France Telecom, SAP, Trusted Logic, AbsInt, Airbus, Alcatel, Daimler, or EADS.

Major progress was also made in 2010 in completing the design, securing the funding, and starting the construction of a permanent building for the Institute on a plot ceded by UPM in the Montegancedo Science and Technology Park. At the time of writing these lines construction is well advanced and on schedule for our move in early 2012.

While much work still lies ahead to achieve the full objectives and dimension of the Institute, it is also clear that it is at this point a vibrant and encouraging reality. My thanks go as always to all of those—too many to list here—that have believed in and contributed to achieving this ambitious goal.

1.1. Profile [7]
1.2. Motivation and Goals [7]
1.3. Legal Status and Management Structure [8]
1.4. Location [9]
1.1. Profile

The IMDEA Software Institute (Madrid Institute for Advanced Studies in Software Development Technologies) is a non-profit, independent research institute promoted by the Madrid Regional Government (CM) to perform research of excellence in the methods, languages, and tools that will allow the cost-effective development of software products with sophisticated functionality and high quality, i.e., safe, reliable, and efficient.

The IMDEA Software Institute belongs to the Madrid Institute for Advanced Studies (IMDEA) network, a new institutional framework created to foster social and economic growth in the region of Madrid by promoting research of excellence and technology transfer in a number of strategic areas (water, food, social sciences, energy, materials, nanoscience, networks, and software) with high potential impact.

1.2. Motivation and Goals

The importance of software is continuously increasing. It is the enabling technology in many devices and services which are now an essential part of our lives, and thus software failures can imply high social and economic cost. Developing software of an appropriate level of reliability, security, and performance, and doing so in a cost-effective manner poses today very significant research challenges. At the same time, because of the ubiquity of software, solutions to these challenges can have a significant and pervasive impact on productivity and on the general competitiveness of the economy.

As mentioned above, the main mission of the IMDEA Software Institute is to perform research of excellence in methods, languages, and tools that will allow the cost-effective development of software products with sophisticated functionality and high quality, i.e., safe, reliable, and efficient. This research focus includes all phases of the development cycle (analysis, design, implementation, validation, verification, maintenance); its distinguishing feature is the concentration on approaches that are rigorous and at the same time allow building practical tools.

In order to achieve its mission, the IMDEA Software Institute is gathering a critical mass of world-wide, top class researchers, and is at the same time developing synergies between them and the already significant research base and industrial capabilities existing in the region. Indeed, although fragmented in different universities and groups, the quality of the research currently performed in the Madrid region in the areas covered by the Institute is competitive at the international level. Also, most of the IT-related companies in Spain (and, specially, their research divisions) are located in the Madrid region, which facilitates collaboration and technology transfer. Thus, the IMDEA
Software Institute brings about the opportunity of having a critical mass of researchers and industrial experts, which can allow for significant improvement in the impact of research.

### 1.3. Legal Status and Management Structure

The IMDEA Software Institute is a non-profit independent organization, constituted as a Foundation. This structure brings together the advantages and guarantees offered by the foundation status with the flexible and dynamic management typical of a private body. This combination is deemed necessary to attain the goals of excellence in research, cooperation with industry, and attraction of talented researchers from all over the world. The Institute was created legally on November 23, 2006, following a design that was the result of a collaborative effort between industry and academia, at the initiative of the Madrid Regional Government, and started its activities during 2007.

The main governing body of the Institute is the Board of Trustees. The Board includes representatives of the Madrid Regional Government, universities and research centers of Madrid, scientists with an international reputation in software development technologies, and representatives of companies, together with independent experts. The Board is in charge of guaranteeing the fulfillment of the foundational purpose and the correct administration of the funds and rights that make up the assets of the Institute, maintaining their appropriate returns and utility. The Board appoints the Director, who is the CEO of the Institute, among scientists with a well-established international reputation in software development technologies. The Director fosters and supervises the activities of the Institute, and establishes the distribution and application of the available funds.
among the goals of the Institute, within the patterns and limits decided by the Board of Trustees. The Director is assisted by the Deputy Director and the General Manager, who take care of the legal, administrative, and financial activities of the Institute.

The Board of Trustees and the Director are assisted in their functions by the Scientific Advisory Board, a scientific council currently made up of 9 scientists from 6 different countries with expertise in different areas of research covered by the Institute. The tasks of this scientific council include: to provide advice on and approve the selection of researchers; to provide advice and supervision in the preparation of yearly and longer-term (4-year) strategic plans; to evaluate the performance with respect to those plans; and to give general advice on matters of relevance to the Institute.

1.4. Location

The IMDEA Software Institute is temporarily located in a newly remodeled floor of the School of Computer Science of the Technical University of Madrid (UPM), in the Montegancedo Science and Technology Park. A new building, entirely devoted to the IMDEA Software Institute, is under construction in a 7,500 m² plot in the Montegancedo Science and Technology Park, which has been ceded to the Institute by UPM for 50 years.
Construction is expected to finish by the end of 2011 and the move into this new facility is planned for early 2012.

This location has excellent access to the UPM Computer Science Department as well as to other new research centers within the Montegancedo Science and Technology Park. These centers include the Madrid Center for Supercomputing and Visualization (CESVIMA), the Montegancedo Campus UPM company “incubator,” the Institute for Home Automation (CEDINT), the Institute for Biotechnology and Plant Genomics (CBGP), the Center for Biomedical Technology (CTB), the Microgravity Institute, and the Spanish User Support and Operations Centre for ISS payloads (USOC). In particular, the CESVIMA is equipped to study massive storage of information, high performance computing, and advanced interactive visualization and houses the second largest supercomputer in Spain and one of the largest in Europe. A number of additional research centers are currently under construction in the campus. The new site will also make use of all the convenient new infrastructures that have been completed recently around the campus, such as the recently opened “Montepríncipe” stop of the Madrid Underground and the newly planned UPM Faculty/Student Residence. The campus has recently obtained the prestigious “International Campus of Excellence” label, and is the only campus in Spain to receive a “Campus of Excellence in Research and Technology Transfer” award in the Information and Communications Technologies area from the Ministry of Science and Innovation.

Board of Trustees

Chairman of the Foundation
Prof. David S. Warren
State University of New York at Stony Brook, USA.

Vice-chairman of the Foundation
Excma. Sra. Dña. Alicia Delibes Liniers
Vice-counselor for Education, Madrid Regional Government, Spain.

Madrid Regional Government
Excma. Sra. Dña. Alicia Delibes Liniers
Vice-counselor for Education, Madrid Regional Government, Spain.
Ilmo. Sr. D. Salvador Victoria Bolívar
Ilmo. Sr. D. José María Rotellar García
Prof. Jorge Sainz
Deputy Director for Research, Madrid Regional Government, Spain. Vice-Chairman of the Foundation.

Universities and Public Research Bodies
Prof. Carmen Fernández Chamizo
Vice-president of Information Technologies and Communications, Universidad Complutense de Madrid, Spain.
Prof. Javier Segovia
Dean of the School of Computer Science, Universidad Politécnica de Madrid, Spain.
Prof. David Ríos Insúa
Vice-president for International Relations and New Technologies, Universidad Rey Juan Carlos, Spain.
Prof. Carmen Peláez Martínez
Vice-president for Research, Consejo Superior de Investigaciones Científicas, Spain.

Scientific Trustees
Prof. David S. Warren
State University of New York at Stony Brook, USA. Chairman of the Foundation.
Prof. Patrick Cousot
École Normale Supérieure de Paris (ENS), France and Courant Institute, New York University, USA.
Prof. Luis Moniz Pereira
Universidade Nova de Lisboa, Portugal.
Prof. José Meseguer
University of Illinois at Urbana Champaign, USA.
Prof. Roberto Di Cosmo
Università Paris 7, France.

Expert Trustees

Mr. José de la Sota
Managing Director, Fundación para el Conocimiento (Madri+D), Madrid, Spain.

Industrial Trustees

BBVA
Mr. Eduardo Sicilia Cavanillas.

Board meetings have been attended, as invitees, by representatives of the following companies:

Telefónica I+D
Mr. Francisco Jariego, Director for Technology Strategy at Telefónica R&D.

Deimos Space
Mr. Miguel Belló Mora, General Director and Mr. Carlos Fernández de la Peña.

Atos Origin
Mr. José María Cavanillas, Director Research & Innovation, and Ms. Clara Pezuela.

Secretary

Mr. Alejandro Blázquez

Scientific Advisory Board

Chairman of the Board

Prof. David S. Warren
State University of New York at Stony Brook, USA.

Prof. María Alpuente
Universidad Politécnica de Valencia, Spain.

Prof. Roberto Di Cosmo
Universitè Paris 7, France.

Prof. Patrick Cousot
École Normale Supérieure de Paris (ENS), France and Courant Institute, New York University, USA.

Prof. Veronica Dahl
University Simon Fraser, Vancouver, Canada.

Prof. Herbert Kuchen
Universität Münster, Germany.

Prof. José Meseguer
University of Illinois at Urbana Champaign, USA.

Prof. Luis Moniz Pereira
Universidade Nova de Lisboa, Portugal.

Prof. Martin Wirsing
Ludwig-Maximilians-Universität München, Germany.

2. Cooperation framework

2.1. Cooperation with Research Institutions [14]
2.2. Cooperation with Industry [14]
2.1. Cooperation with Research Institutions

The Institute offers researchers access to and collaboration with universities and other research centers, in the Madrid region and beyond. The Institute is actively working with these institutions to create a critical mass of researchers capable of producing results which have significant potential impact on industry and society in general. At present the Institute has already signed agreements with the following universities and research centers:

- Universidad Politécnica de Madrid (from November 2007).
- Universidad Complutense de Madrid (from November 2007).
- Universidad Rey Juan Carlos (from January 2008).
- Roskilde University (from June 2008), Denmark.
- Consejo Superior de Investigaciones Científicas (from November 2008).

These agreements establish a framework for the development of collaborations and include the joint use of resources, equipment, and infrastructure, hiring of staff, joint participation in research projects, joint participation in graduate programs, or the association of researchers and research groups with the Institute. To illustrate the scope and importance for the Institute of these agreements, we offer here some highlights. The agreement with the Universidad Politécnica de Madrid includes provisions for the temporary and the permanent locations of the Institute, notably the previously mentioned 7,500 m² plot in the Montegancedo Science and Technology Park ceded to the Institute for 50 years. Under the agreement with the Consejo Superior de Investigaciones Científicas, two of its researchers —Cesar Sánchez and Pedro López— are also part of the research staff of the Institute. Finally, under the agreement with Roskilde University, one of its full professors —John Gallagher— is also part-time senior researcher at the Institute.

2.2. Cooperation with Industry

The IMDEA Software Institute carries out focused collaborations with companies through joint research projects, with both medium and long-term goals, in order to address research challenges in the area of the Institute with potential scientific and economic impact. Listed below are some of the companies with which the IMDEA Software Institute has collaborated to date in joint research projects (the projects are described further in a separate chapter):
Project | Funding Agency | Industrial Partners
--- | --- | ---
MOBIUS | FP6: IP | France Telecom, SAP AG Germany, Trusted Labs
HATS | PF7: IP | Fredhopper
NESSoS | PF7: NoE | Siemens, ATOS
ES_PASS (*) | ITEA2, MITyC | Airbus France, CS Systèmes d’Information, Thales Avionics, Daimler AG, PSA Peugeot Citroen, Siemens VDO Automotive, Astrium SAS, GTD Barcelona, ALCATEL TSD, IFB Berlin
EzWeb | MITyC | Telefónica I+D, Alimerka, Integrasys, Codesyntax, TreeLogic, Intercom Factory, GESIMDE, Yaco, SoftTelecom
DESAFIOS-10 | MICINN | BBVA-GlobalNet, LambdaStream, Deimos Space
PROMETIDOS | Madrid Regional Government | Deimos Space, Atos Origin, BBVA-GlobalNet, Thales, Telefónica I+D
MTECTEST | Madrid Regional Government | Deimos Space

(*) Through associated group at Universidad Politécnica de Madrid.

Other forms of industry collaboration include the participation of company staff in Institute activities, joint participation in Spanish and European Technological Platforms (for example, the Technology Clusters in the Autonomous Community of Madrid or the INES, NESSI and Internet of the Future platforms), joint scholarships for doctorate or masters work (for example, Deimos Space co-funds one PhD in rigorous development of satellite image processing), transfer of research personnel trained by the Institute to companies (for example, Microsoft Redmond co-funds a four-month visit of an IMDEA postdoctoral researcher to explore technology transfer opportunities), access to the Institute's researchers as consultants, access to the Institute's prospective technology and scientific studies (for example, researchers of the Institute have met with personnel from Telefónica I+D, Canal de Isabel II, Ericsson, Interligare, Lingway, GMV, IBM, among many others, to present their main research results), and of course, availability for the creation of joint spin-offs for commercial development of technologies created in the Institute. Given the controversial status of software patents (which have recently faced the opposition not only of notorious public figures such as Linus Torvalds or Tim Berners-Lee but also of the EU Parliament, and which many currently perceive as a hurdle instead of a help for innovation and profit), the IMDEA Software Institute favors the exploitation of its research results through innovative business models, for example those which are based on software products with high technological advantages and which are protected by copyright models that foster their dissemination.

Finally, the IMDEA Software Institute associated companies are hi-tech companies interested in a stable and durable relationship with the Institute. Our industrial trustees fall, of course, into this category. Associated companies participate with the Institute in joint research projects and have special and early access to the activities and results produced. These companies contribute to the sustainability of IMDEA Software, according to their capabilities, the common activities, and their specific areas.
3. Areas of Application [18]
   3.1. Embedded and Real-Time Systems [18]
   3.2. Safety-Critical Systems [18]
   3.3. Security [19]
   3.4. Service Oriented Architectures [19]

3.2. Research Lines [20]
   3.2.1. Modeling [20]
   3.2.2. Software and system security [22]
   3.2.3. Verification and Validation [24]
   3.2.4. Advanced Programming and Optimization Tools [25]
The cost-effective development of complex, safe, reliable, and efficient software is not a simple task, and it cannot be solved by simple “magic bullets” or more enlightened management. The problem affects all stages in the development lifecycle (analysis, design, implementation, verification, maintenance). The IMDEA Software Institute performs research on these aspects along a number of dimensions which include Methodologies (the development and industrial adoption of mathematically rigorous methodologies can improve the software process further), Languages (the basis for expressing software functionality, behavior, and properties), Verification and Validation (semantically well-founded, tool-supported methods to validate code or designs with respect to specifications), and Adequacy/Optimization (the optimal use of resources to achieve a desired goal). To this end:

- The research vision materializes in a number of High-level Research Lines. The current main lines are depicted as rows in Figure 3.1.
- The vision includes also a number of focusing Areas of Application: areas of engineering where the Institute aims and expects to make an impact and which have been identified as priorities in collaboration with industry. The main current areas of application are depicted as columns in Figure 3.1.

These areas of application and high-level research lines are explained further in the rest of the chapter. Finally, two fundamental, cross-cutting issues pervade the vision:

- Tools: well-founded and cost-effective (prototypes of) tools are fundamental study harnesses, demonstrators, and technology transfer vehicles for the techniques for automation of high quality software development.
- Foundations: methods and languages should be built on appropriate mathematical foundations, and at the same time be practical.

![Figure 3.1: Main research lines, application areas, and cross-cutting issues.](image)
3.1. Areas of Application

The following are some areas of application: areas of engineering where the IMDEA Software Institute aims and expects to make an impact.

3.1.1. Embedded and Real-Time Systems

One of the application areas of software where correctness is most critical is embedded systems. An embedded system is a computational artifact that is subject to physical constraints, and whose correct functioning cannot depend on human guidance. In particular, embedded systems are involved in safety-critical applications (such as control systems of automobiles or aircrafts) or systems for highly remote operation (satellite, space, etc.). Embedded systems are also pervasive in areas of high economic impact, like mobile telephony or consumer electronics. Embedded systems must be resource-aware and are often also real-time systems. This means that the computation must be correctly performed within its time constraints, and also with an adequate use of resources. There is a common perception of the potential of rigorous techniques that can improve the quality of embedded software, or the time to market of new devices or families of devices.

Most of the research activities required by embedded and real-time systems and planned at the IMDEA Software Institute are strongly related to the Strategic Research Agenda of the European Technology Platform on Embedded Computing Systems, ARTEMIS.

3.1.2. Safety-Critical Systems

Software is becoming pervasive in areas such as transportation (avionics, automotive), health (diagnosis, therapy), and control (of nuclear plants, of railway signaling systems, of conflict detection systems), where a failure or malfunction may be extremely damaging, even in terms of human lives. The constraints for such safety-critical systems are extremely stringent: the systems must be able to function during extremely long period of times, in presence of human mistakes or hardware or software failures, and provide an acceptable level of services at all times.

Thus, it is urgent to develop methods and tools that help support the development of such dependable
software and its (quantitative) evaluation against the aforementioned constraints. To achieve this goal, it is important to build programming languages and software architectures that facilitate the development of fault-tolerant, resilient, and adaptable applications. One particular challenge is to scale existing methods so that they become effective in the context of distributed and networking systems.

3.1.3. Security

As our society increasingly relies on information technology, there is an urgent and unprecedented need to develop new security mechanisms for protecting infrastructures, data, and applications. Several concomitant factors aggravate the problems of information security.

In order to face this challenge, one must provide scalable and rigorous techniques that can be integrated in prevailing software development processes to enforce security of applications. Since many attacks arise at the application level, it is particularly important to achieve security at the level of programming languages, drawing from methods developed in programming language research (design, analysis, and verification), and developing security solutions at a level of abstraction that matches the programming language.

3.1.4. Service Oriented Architectures

Computer infrastructures are evolving towards highly distributed networks able to provide users with a uniform and global access to services. At the same time, selling services has become the biggest growth business in the IT industry. Service Oriented Architectures (SOAs) are an attempt to provide at the level of software the necessary support for effectively programming, deploying, and maintaining services over highly-distributed networks. SOAs draw from many areas of computer science, including software engineering, concurrent and distributed systems, mobile code, and modular and component-based programming. While these areas are well developed in isolation, there

Figure 3.3: Thousands of services are nowadays directly available on the Internet. This is a huge amount of power to tap from, but it needs to be done in a rational, controlled way in order to ensure correctness, dependability, and quality of service.
remain significant challenges to combine the methodologies that stem from each area in order to deliver cost-effective approaches that support the construction and deployment of electronic services.

Most of the research activities required by SOAs and planned at the IMDEA Software Institute are strongly related to the Strategic Research Agenda of the European Technology Platform on Software and Services (NESSI) and the Future Internet of Services.

3.2. Research Lines

3.2.1. Modeling

A model is an abstraction of some aspect of a system (like a blueprint in engineering), which is created to serve particular purposes, for example, to present a human-understandable description of some aspects of the system or to present information in a form that can be mechanically analyzed. The term Model-Driven Engineering (MDE) is used to describe software development approaches in which abstract models of software systems are created and systematically transformed to obtain concrete implementations or skeletons. Model-driven development holds the promise of reducing system development time and improving the quality of the resulting products.

However, in mainstream MDE practice, models are usually informal, with no well-established semantics, and only used for documentation purposes. In fact, modeling has traditionally been a synonym for producing diagrams. Most models consist of a number of “bubbles and arrows” pictures and some accompanying text. The information conveyed by such models has a tendency to be incomplete, informal, imprecise, and sometimes even inconsistent.
In order to address the major challenges current MDE technologies are facing, we believe that the past and present work on formal methods is particularly relevant. Many of the flaws in modeling are caused by the limitations of the diagrams being used. A diagram simply cannot express some of the essential information of a thorough specification. To specify software systems, formal languages offer some clear benefits over the use of diagrams. Formal languages are unambiguous, and cannot be interpreted differently by different people, for example, an analyst and a programmer. Formal languages make a model more precise and detailed, and are subject to manipulation by automated tools to ensure correctness and consistency with other elements of the model. On the other hand, a model completely written in a formal language is often not easily understood. In this sense, we believe that the interaction between the MDE and formal methods communities has a huge potential impact.

At the IMDEA Software Institute we are providing rigorous semantics for current MDE technologies (e.g., OCL, QVT) and we are developing tool-supported methodologies for applying these technologies for building meaningful models: i.e., models that have a clear and rich meaning, and therefore are useful and valuable for developing quality software. At the same time, we are proposing new MDE technologies for specific areas of applications, including software and system security and graphical user interfaces.

Figure 3.4: A model makes it possible to reason about the relevant properties of a real system. Old-style flowcharts, which model processes, are nowadays substituted by much more powerful representations and methodologies.

Figure 3.5: UML is today’s de facto graphical notation to model systems.
3.2.2. Software and system security

The goal of this line is to develop methods and tools that provide an accurate security analysis of systems and software, together with some countermeasures to defeat malicious agents.

While software security traditionally focuses on low-level protection mechanisms such as access control, the popularization of massively distributed systems dramatically increases the number and severity of vulnerabilities at the application level. These vulnerabilities may be exploited by malicious software such as viruses, Trojan horses, etc., but also (unintentionally) by buggy software, with disastrous effects.

Language-based security aims to achieve security at the level of the programming language, with the immediate benefit of countering application-level attacks at the same level at which such attacks arise. Language-based security is attractive to programmers because it allows them to express security policies and enforcement mechanisms within the programming language itself, using well-developed techniques that facilitate a rigorous specification and verification of security policies.

Language-based techniques can guarantee a wide range of policies including confidentiality, integrity, and availability, and their combination. However, their practical adoption has been hindered partly because known enforcement methods are confined to simple policies, such as non-interference for confidentiality. The most pressing challenges are defining unified enforcement mechanisms that support flexible and cus-
tomizable policies, and developing methods for providing a quantitative assessment of security.

The IMDEA Software Institute is developing rich policy languages that capture precisely common instances of information release. Moreover, these policy languages are directly applicable to powerful abstraction mechanisms that pervade modern programming languages. These policy languages are supported by automated verification procedures, that allow users to detect fraudulent software.

We are also developing accurate methods for a quantitative evaluation of program security. These methods account for covert channels, including timing behavior and resource consumption, and for resistance to common attacks, such as viruses. The ultimate goal is to develop comprehensive adversarial models and effective protection strategies against covert channels.

Language-based methods have been studied primarily for mobile code and very few methods are known to scale to distributed systems. One main challenge is to ensure security of distributed applications, using a combination of cryptographic and language-based methods. Programming language techniques provide an attractive approach to guarantee the security of distributed software, because they allow reasoning about programs and their cryptographic libraries in a unified framework. Moreover, programming language techniques are rigorous, and thus are useful to demonstrate beyond reasonable doubt that standard cryptographic systems, some of which have a long history of flawed security proofs and hidden but effective attacks, are secure.

The IMDEA Software Institute is building tools that support the automated analysis of cryptographic systems and provide very strong guarantees of their correctness (cryptographic strength). The tools adopt the game-playing technique, that organizes the construction of cryptographic proofs as sequences of probabilistic games as a natural solution for taming the complexity of performing cryptographic proofs. The tools have been validated experimentally through the verification of widely deployed cryptographic standards.

Figure 3.7: The term “bug” originated in one of the first computers, where a real bug caused a short-circuit and therefore an error in a program whose reason remained undiscovered until the insect was found in the computer’s circuitry. Today, “bug” is a synonym for hard-to-catch problem which causes malfunctions in software.
3.2.3. Verification and Validation

Verification refers to the rigorous demonstration that software is correct; that is, it provides behavioral consistency according to a given specification of its intended behavior. By “intended behavior” we mean the properties that software is expected to satisfy when it is deployed. Software not possessing the properties might be defective: its execution might have unintended consequences. Verified software is software that is free of certain classes of defects because it has been rigorously proven that it satisfies its intended behavior. For these particular classes of defects, the verified software is termed zero-defect software. Such software does not require disclaimers that forgive developer error. Instead such software is guaranteed to be reliable — it behaves as intended.

How do we “rigorously prove” that software is correct? The basic principle is to represent properties as logical formulas so that verification of the properties is akin to proving a theorem using proof techniques from mathematical logic. However, modern software is very complex and typically composed of several components, where each component can be written in a different programming language. For such complex software, proving properties manually is very difficult. The question that arises naturally is this: can the logic-based proof techniques be made to scale so that software can be automatically verified as much as possible so that the manual verification burden is minimized? Apart from managing the complexity of proofs, the benefits of automatic verification are as follows. First, the verification can be repeated whenever necessary and with the same results, thus attesting to the accuracy of verification. Second, proofs can be mechanically checked for correctness. Third, verification results can be reused: once a program has been verified, its specifications can be repeatedly used in verification of a larger piece of software without re-verification.

Researchers at the IMDEA Software Institute are involved in various aspects of automatic software verification. They study expressive languages and logics for specification of properties of software, particularly of software written in modern programming languages such as Java. Once a Java program is decorated with such specifications, off-the-shelf verifiers can be used to generate “verification conditions” which can then be discharged by theorem provers. Researchers are not only studying more efficient
verification algorithms and decision procedures for improving theorem proving technology, but also are performing experiments on verifying realistic code such as Java libraries — whose programs are frequently used in building complex software — and design patterns, which provide generic solutions to common software problems. The automated proofs will be made publicly available in a repository linked to the Verified Software Repository of the international Verification Grand Challenge Project.

3.2.4. Advanced Programming and Optimization Tools

The goal of this line is to develop methods and tools that help programmers improve the quality and robustness of the programs they write, allow them to write better programs in a shorter time, and support efficient execution of code through highly optimizing compilers.

Regarding program correctness and robustness the aims are similar to those in verification, but the focus here is on tools that find errors and verify programs during the process of writing such programs, rather than a posteriori. This focus requires efficient and fully automatic program analysis methods.

Abstraction-based techniques provide a unifying framework for this purpose. Their essence is abstract interpretation, a rigorous method which induces a dramatic reduction in the complexity of software analysis. It has been shown powerful enough to, for example, analyze automatically avionics software, a clear example of a large cyber-physical system, consisting of millions of lines of code, and subject to stringent conditions from the DO-178B standards. Researchers at the IMDEA Software Institute are developing tools that show that abstraction techniques can be embedded in development environments for routine use by programmers for on-line debugging, diagnosis, verification, and certificate generation, and that they combine naturally with (and reduce the need for) other techniques such as testing and run-time verification, which currently take more than 90% of overall development cost.
Abstraction-based techniques have also been shown particularly effective for high integrity and embedded software, where the properties of concerns are time and memory consumption, dynamic data sizes, energy consumption, termination, absence of errors or exceptions, etc. Researchers at the IMDEA Software Institute are developing advanced tools for debugging and verification of software with respect to these non-functional properties.

Another important way of improving the programming process, which allows programmers to write better programs in a shorter time, is by improving programming languages. Researchers at the IMDEA Software Institute are working on promising approaches such as extensible and multi-paradigm languages, support for domain-specific languages, support for multi-language applications, and service-oriented architectures.

Regarding the objective of supporting the efficient execution of code, abstraction-based techniques can also be used to ensure that programs are highly optimized before execution, i.e., that they run in the fastest and most resource-efficient way on the platforms and environmental conditions they are deployed on, while maintaining their observable behavior. Typical goals include saving on memory and processing time on sequential processors, adaptive task scheduling in parallel and distributed computers, self-reconfiguration, and automatic adaptation to environmental conditions.

A prominent form of such program optimization is automatic parallelization. As highly parallel processors are becoming an inexpensive and common facility in mainstream computing, there is an opportunity to build much faster, and eventually much better, software. Yet exploiting this enormous potential requires the development of new programming practices that reflect this profound change in the execution paradigm. Two common alternatives are to write parallel programs, using dedicated programming idioms and algorithms that help taming the complexity of parallel programs, or to automatically parallelize existing ones, using compilers for identifying parts of the application that are independent and can thus be run in parallel. Researchers at the IMDEA Software Institute are working on both approaches, developing languages and idioms more suited for parallelism and abstraction-based techniques and tools for allowing detection of common errors in parallel programs and for automatic parallelization of programs.

4.3. Visiting Faculty [39]
4.4. Research Assistants - Ph.D. Students [39]
4.5. Interns [41]
4.6. Administration & IT Support [41]
The IMDEA Software Institute strives towards excellence and being competitive with the highest-ranked institutions worldwide. To be successful in this goal, the Institute must attract highly-skilled personnel for the scientific teams and support staff. This is one of the main goals of the Institute, to the point of considering it a fundamental measure of its success.

Competition for talent in this area is extremely high at the international level, since essentially all developed countries have identified the tremendous impact that IT has on the economy and the crucial competitive advantage that attracting truly first class researchers entails. To meet this challenge the Institute is creating a world-class working environment that is competitive with similar institutions in Europe and in the US and combines the best aspects of a university department and a research laboratory.

Hiring follows internationally-standard open dissemination procedures with public, international calls for applications launched periodically. These calls are advertised in the appropriate scientific journal(s) and at conferences in the area, as well as in the Institute web page and mailing lists. Appointments at (or promotion to) the Assistant Professor, Associate Professor, and Full Professor levels (i.e., tenure-track hiring, tenure, and promotion decisions) are approved by the Scientific Advisory Board. Figures 4.1 and 4.2 show the number of applications received during 2010 and the location (by continents) of the institutions from which they applied (for senior, junior, and postdoctoral positions). Spain is highlighted separately from Europe in order to provide a finer view of the data.

**Figure 4.1:** Applications received (organized by positions requested).

**Figure 4.2:** Locations of applicants' institutions (only for senior, junior, and postdoc positions), organized by continents.
In addition to staff positions the Institute has its own program of high-quality graduate scholarships, internships, and visiting researchers. In all aspects related to human resources, the Institute follows the recommendations of the European Charter for Researchers and a Code of Conduct for their Recruitment (http://ec.europa.eu/), which it has duly signed.

Currently, the scientific staff of the Institute is composed of 5 Full or Associate professors (plus one part-time), 9 assistant professors (3 non tenure-track), 7 postdoctoral researchers, 10 PhD students, and 5 interns. A number of visitors have also been at the Institute during 2010. Figures 4.3 and 4.4 summarize, respectively the nationalities of full and associate professors (seniors), assistant professors (juniors), and postdoctoral researchers, and the places from where they obtained their PhD degrees. It can be noted that 64% of IMDEA researchers were born abroad, and 77% received their PhD degree from universities either located in another European country or the US.
Manuel Hermenegildo received his Ph.D. degree in Computer Science and Engineering from the University of Texas at Austin, USA, in 1986. Since January 1, 2007 he is Full Professor and Scientific Director of the IMDEA Software Institute. He is also a full Prof. of Computer Science at the Tech. U. of Madrid, UPM. Previously to joining the IMDEA Software Institute he held the P. of Asturias Endowed Chair in Information Science and Technology at the U. of New Mexico, USA. He has also been project leader at the MCC research center and Adjunct Assoc. Prof. at the CS Department of the U. of Texas, both in Austin, Texas, USA. He has received the Julio Rey Pastor Spanish National Prize in Mathematics and Information Science and Technology and the Aritmel National prize in Computer Science, and he is an elected member of the Academia Europaea. He is also one of the most cited Spanish authors in Computer Science. He has published more than 150 refereed scientific papers and monographs and has given numerous keynotes and invited talks in major conferences in these areas. He has also been coordinator and/or principal investigator of many national and international projects, area editor of several journals, and chair and PC member of a large number of conferences. He served as general director for the research funding unit in Spain, as well as member of the European Union’s high-level advisory group in information technology (ISTAG), and of the board of directors of the Spanish Scientific Research Council and the Center for Industrial and Technological Development, among other national and international duties.

Research Interests
His main areas of interest include programming language design and implementation; abstract interpretation-based program analysis, verification, debugging and optimization; logic and constraint programming; parallelizing compilers; parallel and distributed processing.
Manuel Clavel received his Bachelor's degree in Philosophy from the Universidad de Navarra in 1992, and his Ph.D. from the same university in 1998. Currently, he is Deputy Director and Associate Research Professor at the IMDEA Software Institute, as well as Associate Professor at the Universidad Complutense de Madrid. During his doctoral studies, he was an International Fellow at the Computer Science Laboratory of SRI International (1994 - 1997) and a Visiting Scholar at the Computer Science Department of Stanford University (1995 - 1997). His Ph.D. dissertation was published by the Center for the Study of Language and Information at Stanford University. Since then, he has published over 30 refereed scientific papers. He has also been involved in the supervision of 3 Ph.D. students (1 completed).

Research Interests
His research focuses on rigorous, tool-supported model-driven software development, including: modeling languages, model transformation, model quality assurance, and code-generation. Related interests include specification languages, automated deduction, and theorem proving.

Gilles Barthe received a Ph.D. in Mathematics from the University of Manchester, UK, in 1993, and an Habilitation à diriger les recherches in Computer Science from the University of Nice, France, in 2004. He joined the IMDEA Software Institute in April 2008. Previously, he was head of the Everest team on formal methods and security at INRIA Sophia-Antipolis Méditerranée, France, and a member of the Microsoft Research-INRIA Joint Centre. He also held positions at the University of Minho, Portugal; Chalmers University, Sweden; CWI, Netherlands; University of Nijmegen, Netherlands. He has published more than 100 refereed scientific papers. He has been coordinator/principal investigator of many national and European projects, and served as the scientific coordinator of the FP6 FET integrated project "MOBIUS: Mobility, Ubiquity and Security" for enabling proof-carrying code for Java on mobile devices (2005-2009). He has been a PC member of many conferences (CSF, ESORICS, FM, ITP...), and served as PC (co-)chair of VMCAI’10, ESOP’11, FAST’11, and SEFM’11. He is a member of the editorial board of the Journal of Automated Reasoning.

Research Interests
Gilles’ research interests include formal methods, programming languages and program verification, software security, and cryptography, and foundations of mathematics and computer science. His most recent research focuses on the automated certification of cryptographic schemes, and on correctness and security analyses of Java bytecode.
Anindya Banerjee
Professor

Anindya Banerjee received his PhD from Kansas State University, USA, in 1995. After his PhD, Anindya was a postdoctoral researcher, first in the Laboratoire d’Informatique (LIX) of École Polytechnique, Paris and subsequently at the University of Aarhus. He joined the IMDEA Software Institute in February 2009 as Full Professor. Immediately prior to this position, Anindya was Full Professor of Computing and Information Sciences at Kansas State University, USA. He was an Academic Visitor in the Advanced Programming Tools group, IBM T. J. Watson Research Center in 2007 and a Visiting Researcher in the Programming Languages and Methodology group at Microsoft Research in 2007-2008. He was a recipient of the Career Award of the US National Science Foundation in 2001.

Research Interests
Anindya’s research interests lie in language-based computer security, program analysis and verification, program logics, concurrency, programming language semantics, abstract interpretation and type systems. His primary research activities over the past couple of years have centered around automatic, modular verification of properties of pointer-based programs and in proving security properties such as confidentiality and integrity properties of programs.

César Sánchez
Assistant Professor

César Sánchez received his Ph.D. degree in Computer Science from Stanford University, USA, in 2007, studying formal methods for distributed algorithms. After a post-doc at the University of California at Santa Cruz, USA, César joined the IMDEA Software Institute in 2008, becoming a Scientific Researcher at the Spanish Council for Scientific Research (CSIC) in 2009. He holds a degree in Ingeniería de Telecomunicación (MSEE) from the Technical University of Madrid (UPM), Spain, in 1998. Funded by a Fellowship from La Caixa, he moved to Stanford University, USA, receiving a M.Sc. in Computer Science in 2001, specializing in Software Theory and Theoretical Computer Science. César is a recipient of the 2006 ACM Frank Anger Memorial Award. He keeps active collaborations with research groups in the USA and Europe.

Research Interests
César’s research activities focus on formal methods for reactive systems with emphasis on the development and verification of concurrent, embedded and distributed systems. His foundational research includes the temporal verification of concurrent datatypes, runtime verification, and enhancements of linear temporal logics. In parallel, he is collaborating with industrial partners from the aerospace and embedded sectors to aid in the adoption of formal techniques for software development and validation. Current projects include the interactive formal generation of parallel software for satellite image processing, and the synthesis of advanced online debuggers for testing embedded software.
Pierre Ganty  
Assistant Professor

Pierre joined the IMDEA Institute in September 2009 after completing a nearly two year postdoc at the University of California, Los Angeles (UCLA). He holds a joint PhD degree in Computer Science from the University of Brussels (ULB), Belgium and from the University of Genova (Unige), Italy that he obtained late 2007. Prior to his PhD, he completed a master and a DEA in computer science from the ULB that he obtained in 2002 and 2004, respectively. During his postdoc, Pierre has been nominated for a campus wide UCLA Chancellor’s Award for Post-doctoral Research (15 nominees/1089 postdoctoral scholars).

Research Interests
Pierre’s research studies automated analysis techniques for systems with infinitely many states. Many systems are, by nature, infinite and cannot be modeled precisely with finitely many states. Of particular interests are concurrent systems like multithreaded programs or communication protocols or event-based programs. In each of the above classes of systems, there is an unbounded dimension: the number of threads, the number of participants or the number of events, which is best modeled using an infinite state system.

In theory, the analysis of such systems is infeasible unless some precision is lost. In his previous works, he defined over approximation analysis techniques which are useful to prove properties on such systems. His current research has a strong emphasis on complementary under approximation techniques which do not offer complete coverage but are relevant to catch bugs in those systems.

Aleks Nanevski  
Assistant Professor

Aleks received his Ph.D. degree in Computer Science from Carnegie Mellon University, USA in 2004. After holding postdoctoral positions at Harvard University (USA), and Microsoft Research, Cambridge (UK), Aleks joined the IMDEA Software Institute in September 2009. Prior to the PhD, Aleks finished his undergraduate studies in Computer Science at the University of Skopje, Macedonia in 1995.

Research Interest
Aleks’ research is in the design and implementation of programming languages that facilitate verification of various program properties, ranging from type and memory safety, lack of memory leaks or information leaks, all the way to full functional correctness. His languages and systems unify programming and specification with automated and interactive theorem proving, via a common foundational framework of type theory. He is particularly interested in verifying programs that combine modern higher-order linguistic features such as higher-order functions, polymorphism, abstract types, objects and modules, with imperative ingredients such as pointer arithmetic, pointer aliasing, unstructured control flow, and concurrency.
Alexey Gotsman
Assistant Professor

Alexey Gotsman received his Ph.D. degree in Computer Science from University of Cambridge, UK in 2009. During his Ph.D. studies, Alexey interned at Microsoft Research Cambridge, UK and Cadence Berkeley Labs, USA. He was a postdoctoral fellow at Cambridge before joining IMDEA in September 2010. Prior to his Ph.D., Alexey did his undergraduate and master studies in Applied Mathematics at Dnepropetrovsk National University, Ukraine, interning at the University of Trento, Italy in the process.

Research Interests
Alexey's research interests are in software verification, with particular focus on concurrent systems software. He is interested in developing both logics for reasoning about programs and automatic tools for verifying them. Alexey's research activities include development of such logics and tools for concurrent programs with data structures, liveliness properties, and operating systems.

Boris Köpf
Assistant Professor

Boris joined the IMDEA Software Institute in September 2010 after completing a post-doc at the Max Planck Institute for Software Systems (MPI-SWS). He received a Ph.D. degree from ETH Zurich in 2007, investigating formal methods for counteracting side-channel attacks. Before that, he studied mathematics at the Universidad de Chile, the Universidade Federal de Campinas, and the University of Konstanz, from which he received a M.Sc. degree. He is an alumnus of the German National Academic Foundation.

Research Interests
Boris' research focuses on information security, formal verification, and algorithm design. In particular, he is interested in designing metrics for quantifying the security of systems, and in developing techniques and tools for computing these metrics. His favorite application domain is the analysis of side-channels in cryptographic algorithms and in web-traffic.

Juan Caballero
Assistant Professor

Juan Caballero joined the IMDEA Software Institute as an Assistant Research Professor in November 2010, after receiving his Ph.D. degree in Electrical and Computer Engineering from Carnegie Mellon University, USA. Prior to joining the IMDEA Software Institute, Juan was a visiting graduate student researcher at University of California, Berkeley for two years. He was awarded the La Caixa fellowship for graduate studies in 2003. Juan also holds a M.Sc. in Electrical Engineering from the Royal Institute of Technology (KTH), Sweden, and a Telecommunications Engineer degree from the Technical University of Madrid (UPM), Spain.

Research Interests
Juan's research focuses on computer security, including security issues in systems, software, and networks. He enjoys designing program analysis techniques, specially techniques that work directly on program binaries. He applies those techniques for analyzing security properties of benign programs, as well as for malware analysis. In addition, he is interested in network security, the economic aspects of cybercrime, applying machine learning for security, and software engineering.
Pedro López-García
Researcher

Pedro López-García received a MS degree and a Ph.D. in Computer Science from the Technical University of Madrid (UPM), Spain in 1994 and 2000, respectively. In May 28, 2008 he got a Scientific Researcher position at the Spanish Council for Scientific Research (CSIC) and joined the IMDEA Software Institute. Immediately prior to this position, he held associate and assistant professor positions at UPM and was deputy director of the Artificial Intelligence unit at the Computer Science Department. He has published about 30 refereed scientific papers (50% of them at conferences and journals of high or very high impact.) He has also been coordinator of the international project ES_PASS and participated as a researcher in many other national and international projects.

Research Interests
His main areas of interest include automatic analysis and verification of global and complex program properties such as resource usage (user defined, energy, execution time, memory, etc.), non-failure and determinism; performance debugging; (automatic) granularity analysis/control for parallel and distributed computing; profiling; combined static/dynamic verification and unit-testing; type systems; constraint and logic programming.

Mark Marron
Researcher

He received his Ph.D. from the University of New Mexico under the supervision of Deepak Kapur. He joined the IMDEA Software Institute as a postdoctoral researcher in June 2008.

Research Interests
His research interests are on developing practical techniques for modeling program behavior and using this information to support error detection and optimization applications. His work to date has focused on the development of static analysis for the program heap which infers region, sharing, footprint and heap based data-dependence information. More recent work has focused on using the information extracted by the analysis to support program parallelization, memory management, error detection, and software engineering applications.

Laurent Mauborgne
Researcher

Laurent Mauborgne received his Ph.D. in Computer Science from Ecole Polytechnique, France, in 1999, and an Habilitation a diriger les recherches from University Paris-Dauphine (France) in 2007. He has been assistant professor at Ecole normale superieure, Paris, since 2000, and associate director of computer science studies there since 2006. He was also part-time professor at Ecole polytechnique. He was invited to spend a year at the IMDEA Software Institute in August 2009.

Research Interests
The research of Laurent Mauborgne is focused on static analysis of programs and abstract interpretation. The goal is to develop theoretical as well as practical tools to analyze the behaviors of programs. This includes proving safety or temporal properties, optimizing compilation and computing resource usage. Among the recent subjects, he studied the cooperative combination of analyses in different frameworks.
Juan José Moreno-Navarro
Professor (on leave)

Juan José Moreno-Navarro received his Ph.D. degree in Computer Science from the Technical U. of Madrid (UPM), Spain in 1989. He developed a large part of his Ph.D. at RWTH Aachen (Germany). From 1984-1987 he was employed in research and development in a software company in Hamburg, Germany. Between 1990 and 2002 he was a lecturer and later senior lecturer at the University of Bristol, UK. Since 2002 he has been a professor at the University of Roskilde, Denmark, where he is leader of the research group Programming, Logic and Intelligent Systems as well as (part-time) Professor and holds a dual appointment at the IMDEA Software Institute since February 2007. He is a member of the executive committee of the Association of Logic Programming and of the steering committee of the ACM SIGPLAN workshop series on Partial Evaluation and Program Manipulation (PEPM). He is an editorial advisor to the journal Theory and Practice of Logic Programming. He has published approximately 50 peer-reviewed papers which have over 1200 citations.

Research Interests
His research interests focus on program transformation and generation, program analysis, constraint logic programming, rewrite systems, temporal logics, semantics-based emulation of languages and systems, and verification using abstraction and has participated in a number of national and European research projects on these topics.

John Gallagher
Professor (part-time)

John Gallagher received the B.A. (Mathematics with Philosophy) and Ph.D. (Computer Science) degrees from Trinity College Dublin in 1976 and 1983 respectively. He held a research assistantship in Trinity College (1983-4), and post-doc appointments at the Weizmann Institute of Science, Israel (1987-1989) and Katholieke Universiteit Leuven, Belgium (1989). From 1984-1987 he was employed in research and development in a software company in Hamburg, Germany. Between 1990 and 2002 he was a lecturer and later senior lecturer at the University of Bristol, UK. Since 2002 he has been a professor at the University of Roskilde, Denmark, where he is leader of the research group Programming, Logic and Intelligent Systems as well as (part-time) Professor and holds a dual appointment at the IMDEA Software Institute since February 2007. He is a member of the executive committee of the Association of Logic Programming and of the steering committee of the ACM SIGPLAN workshop series on Partial Evaluation and Program Manipulation (PEPM). He is an editorial advisor to the journal Theory and Practice of Logic Programming. He has published approximately 50 peer-reviewed papers which have over 1200 citations.

Research Interests
His research interests focus on program transformation and generation, program analysis, constraint logic programming, rewrite systems, temporal logics, semantics-based emulation of languages and systems, and verification using abstraction and has participated in a number of national and European research projects on these topics.
César Kunz
Postdoctoral Researcher

César Kunz received a Computer Science degree from the National University of Córdoba (UNC), Argentina in 2004. He continued his studies at INRIA, France, funded by the FP6 FET integrated project «MOBIUS: Mobility, Ubiquity and Security», and received a Ph.D. from the École des Mines de Paris (ENSMP), France in February 2009. He joined the IMDEA Software Institute as a postdoctoral researcher in February 2009.

Research Interests
His research interests lie around formal program analysis and verification, abstract interpretation, and program transformation. His primary research activities are centered on the certification of program correctness, the verification of compiler optimizations, and the transformation of verification results in the presence of program transformations.

Daniel Hedin
Postdoctoral Researcher

He received his Ph.D. from Chalmers University of Technology under the supervision of David Sands. He joined the IMDEA Software Institute as a postdoctoral researcher in November 2008.

Research Interests
His research interests are on static analysis of programs, and formal verification of program analyses. His earlier work revolved around type based enforcement of noninterference, together with formalizations of their correctness in Coq. Recent work has been focused on formal certification of game based crypto proofs using CertiCrypt, and exploring the possibility of automating such proofs.

Marina Egea
Postdoctoral Researcher

Marina Egea is holding a postdoctoral position at IMDEA Software Institute. Previously she held a postdoctoral position in the Information Security Group at ETH Zurich. She received her doctoral degree in Computer Science at the University Complutense of Madrid in 2008. Her thesis proposes an executable formal semantics for a significant subset of OCL, which is based on a novel mapping from UML models with OCL expressions to equational theories which are proved to be Church-Rosser and terminating and are shown to allow rigorous analysis and validation of the corresponding model. She received her bachelor degree in Mathematics from the University of Granada in 2001, and her Master Thesis from the University Complutense of Madrid in 2005 by the Department of Computer Science.

Research Interests
Her research focuses on the use of formal methods for improving the quality of software engineering products. She is actively involved in the development of a research line on rigorous, tool-supported modeling and validation of software systems. Some of her recent and current research focuses on integrating security policies in system design models and automatically analyzing the resulting model, automatically transforming system design models (including security properties) in a provably correct way, and on bridging the gap between the software design and deployment by helping the fully automation of the code generation.
Alexander Malkis
Postdoctoral Researcher

Alexander has obtained his Diploma degree from the University of Saarland, Germany, in 2004-2005, for a work on polyforms (in other terminology, bond animals) under the guidance of Prof. Dr. Raimund Seidel; during his studies Alexander was financed by the prominent foundation “Studienstiftung des deutschen Volkes”. He continued his studies in Saarbruecken and Freiburg, funded by the Max-Planck society and the DFG (German science foundation), obtaining his PhD thesis in 2010 at the University of Freiburg for a work on verification of multithreaded programs under guidance of Prof. Dr. Andreas Podelski. In April 2010, he joined IMDEA Software.

Research Interests
There is a range of topics in which Alexander is interested in, among them: polynomial verification of large program classes; emptiness of language intersection (complexity and algorithms); thread simulations, liveness, procedure abstractions under concurrency; a working verifier for multithreaded C; verifying multithreaded programs with rich structure and semantics, e.g. with heap, probabilism, recursion, for multicore systems; modeling biological and social systems; and synthesis of multithreaded embedded software.

José Francisco Morales
Postdoctoral researcher

Jose F. Morales joined the IMDEA Software Institute as a postdoctoral researcher in November 2010, after receiving his Ph.D degree in Computer Science from the Technical University of Madrid (UPM), Spain. Previously, he held a teaching assistant position at the Universidad Complutense de Madrid, starting in 2005. Jose's work to date has focused on mechanisms for the efficient execution of logic programs: inference of program properties by abstract interpretation, highly-optimizing translation to low-level code using those properties, and the development of abstractions for the specification and automated construction of abstract machines.

Research Interests
His current research interests include the design of multiparadigm languages (combining imperative, logic, functional, and object-oriented programming), assertion languages and type systems, abstract interpretation, abstract machines, compiler optimizations, and native code generation.

Ruy Ley-Wild
Postdoctoral researcher

Ruy Ley-Wild joined the IMDEA Software Institute as a postdoctoral researcher in December 2010. He received his Ph.D. degree in Computer Science from Carnegie Mellon University under the supervision of Guy Blelloch. During his Ph.D. studies, he was funded by a Bell Labs Graduate Research Fellowship and interned at Bell Labs, Toyota Technological Institute at Chicago, and Microsoft Research Cambridge.

Research Interests
Ruy is broadly interested in the design and implementation of programming languages that express computation at a suitable level of abstraction and logics that enable high-level reasoning about the correctness and complexity of such programs. In particular, he has worked on compilation, cost semantics, and high-level dependence-tracking for self-adjusting computation. He is currently working with Aleks Nanevski on a type-theoretic approach to semantics and logics for a higher-order, stateful, concurrent language.

Santiago Zanella Béguelin
Postdoctoral researcher

Santiago Zanella Béguelin obtained his degree in Computer Science from Universidad Nacional de Rosario (UNR), Argentina in 2006. He received his Ph.D. degree from École Nationale Superieure des Mines de Paris in 2010 under the supervision of Gilles Barthe. From 2006 to 2010 he was a member of the Secure Distributed Computations and their Proofs team at the Microsoft Research-INRIA Joint Centre, Paris. He joined IMDEA in November 2009.

Research Interests
His main areas of interest include program specification and verification, quantitative analysis of programs, security proofs of cryptographic systems, language-based security, and proof assistants.

Santiago has devised novel program logics and programming language techniques that can be used to establish the security of cryptographic systems with an unprecedented level of assurance, making a jump from qualitative to quantitative guarantees, and from informal arguments to fully formalized, independently verifiable proofs. These ideas have been realized in the CERTICRYPT framework, and applied to obtain certified security proofs of prominent and practically-relevant cryptographic systems, such as the Optimal Asymmetric Encryption Padding (OAEP) scheme. He is currently working on developing automated tools to bring verification of security of cryptographic systems to practice, using off-the-shelf SMT solvers and automated theorem provers.

research assistants ph.d. students

Álvaro García
Research Assistant
Degree: Technical University of Madrid (UPM), Spain.
Research: Type theory, dependent types and genericity, in particular how to extend dependent types in a modular way, with regards to the expression problem.

Miguel Ángel García de Dios
Research Assistant
Degree: Universidad Complutense, Spain.
Research: Formal specification and verification, and rigorous tool supported modeling and validation of software systems.

Julián Samborski-Forlese
Research Assistant
Degree: Universidad Nacional de Rosario (UNR), Argentina.
Research: Applications of formal methods and abstract interpretation to program verification; quantum computing; functional programming languages; semantics.

Juan Manuel Crespo
Research Assistant
Degree: Universidad Nacional de Rosario (UNR), Argentina.
Research: Programming language semantics, type theory, functional programming, category theory, logic and software verification.
Federico Olmedo
Research Assistant
Degree: Universidad Nacional de Rosario (UNR), Argentina.
Research: Verification of cryptographic systems and semantics of programming languages.

Teresa Trigo
Research Assistant
Degree: Technical University of Madrid (UPM), Spain.
Research: Software verification techniques based on static analysis and its application to embedded systems. Resource usage analysis and automatic parallelization.

Antonio Artés
Research Assistant
Degree: Technical University of Madrid (UPM), Spain.
Research: Power-aware, temperature-aware and reliability-aware design of low power semiconductor devices.

Alejandro Sánchez
Research Assistant
Degree: Universidad Nacional de Córdoba (UNC), Argentina.
Research: Formal methods, program verification, dynamic memory analysis, concurrent systems, type theory, functional programming.

Carolina Inés Dania
Research Assistant
Degree: Universidad Nacional de Córdoba (UNC), Argentina.
Research: Tool-supported model-driven software development. Oriented on formal specification languages, security models, transformation and code generation.

Javier Valdazo Parnisari
Research Assistant
Degree: Universidad Nacional de Córdoba (UNC), Argentina.

administration & IT support
5.1. Ongoing Projects [43]
5.2. Projects with Associated Groups [47]
5.3. Recently Granted Projects (not started in 2010) [47]
5.4. Recently Finished Projects [50]
5.5. Fellowships [53]
Research activities and technology transfer for industry are normally carried out within the framework of research projects funded by national or international funding agencies or directly through contracts with industry. The IMDEA Software Institute is currently participating (and has participated) in a number of research projects which are briefly summarized below.

5.1. Ongoing Projects

**AMAROUT Europe**

**Funding:** European Union, Marie Curie Action (PEOPLE-COFUND) - 7th Framework Program  
**Duration:** 2009-2013  
**General Coordinator:** Prof. Manuel Hermenegildo

AMAROUT Europe is a Marie Curie Action (PEOPLE-COFUND) to foster and consolidate the European Research Area by attracting to Europe and, in particular, to the region of Madrid (Spain) top research talent. AMAROUT contributes with IMDEA to the goal of turning Madrid into one of the top knowledge generation regions in Europe. To accomplish this, the AMAROUT program finances up to 132 researchers to join the IMDEA network of research institutes for one year (renewable up to twice). The total budget for the program is around 11 M Euros of which the European Union cofinances 40%.

Both “experienced” and “very experienced” researchers from any country (worldwide) can apply for AMAROUT fellowships at any of the eight IMDEA Institutes participating in the program (Software, Energy, Food, Materials, Nanoscience, Networks, Water, and Social Sciences). The AMAROUT Selection Committee consists of eight Evaluation Panels, one for each of the participating IMDEA Institutes. Each Evaluation Panel is formed by the Director of the Institute, three members of its Scientific Advisory Board, and two external, independent peer reviewers. The main AMAROUT selection criteria is the candidate’s demonstrated ability and commitment to research, as well as the match of experience and interests with the research theme and lines of the IMDEA Institute chosen by the candidate.

The AMAROUT Program is a joint-initiative from eight IMDEA research institutes. The IMDEA Software Institute operates as the beneficiary. As such, IMDEA Software is also in charge of the project management structure: Scientific Committee (SC); Fellowships Management Unit (FMU); Secretary and Local Board of Prospective (BP). The FMU is responsible for the overall program management. IMDEA Software chairs the project team meetings (quarterly). The FMU is supported in its activities by the Secretary (administration, financial, H&M, welcoming) to fulfill the personnel-related, administrative and financial requirements of the Program and the EC. The secretary is commanded by the IMDEA Software. The SC is responsible of the definition of the scientific lines and of the appraisal of the correct implementation of the scientific Program. The IMDEA Software director is the leader of the SC.
HATS
Highly Adaptable and Trustworthy Software using Formal Models

Funding: European Union, FET Focused Call Forever Yours – 7th Framework Program
Duration: 2009-2013
Principal Investigator: Prof. Gilles Barthe

HATS is an Integrated Project funded by the European Union within the 7th Framework Program. The main outcome envisaged by this project is an integrated architectural framework and a methodology for rigorous development of highly adaptable and trustworthy software. The IMDEA Software Institute is one of the research centers in a consortium of 8 academic partners, 2 industrial research centers, and 1 SML, from 7 countries. The budget for the project is approximately 6 M Euros.

Software systems are central for the infrastructure of modern society. To justify the huge investments such systems need to live for decades. This requires software which is highly adaptable. Software systems must support a high degree of spatial variability to accommodate a range of requirements and operating conditions, and temporal evolvability to allow these parameters to change over time.

Current approaches to reusability and maintenance are inadequate to cope with the dynamics and longevity of future software applications and infrastructures, e.g. for e-commerce, e-health and e-government. At the same time, we rely increasingly on systems that provide a high degree of trustworthiness. The major challenge facing software construction in the next decades is high adaptability combined with trustworthiness.

A severe limitation of current development practices is the missing rigor of models and property specifications. Without a formal notation of distributed, component-based systems it is impossible to achieve automation for consistency checking, enforcement of security, generation of trustworthy code, etc. Furthermore, it does not suffice to simply extend current formal approaches. We propose to take an empirically successful, yet informal software development paradigm and put it on a formal basis.

Specifically, in HATS we will turn software product family (SWPF) development into a rigorous approach. The technical core of the project is an Abstract Behavioral Specification language which will allow precise description of SWPF features and components and their instances. The main project outcome is a methodological and tool framework achieving not merely far-reaching automation in maintaining dynamically evolving software, but an unprecedented level of trust while informal processes are replaced with rigorous analyses based on formal semantics.

The IMDEA Software Institute is responsible for the development of a highly adaptable architecture that allows cost-effective verification of the executable programs that will
be automatically generated from Abstract Behavioral Specifications. The security architecture will be specifically directed towards security policies expressed using information flow and functional correctness policies.

**NESSoS**

Network of Excellence on Engineering Secure Future Internet Software Services and Systems

**Funding:** European Union, Cooperation Program (NoE) – 7th Framework Program

**Duration:** 2010-2013

**Principal Investigator:** Prof. Manuel Clavel

The Network of Excellence on Engineering Secure Future Internet Software Services and Systems (NESSoS) aims at constituting and integrating a long lasting research community on engineering secure software based services and systems. The NESSoS consortium involves 12 partners, including 2 companies (namely, Siemens and ATOS), from 7 countries. The budget for the project is approximately 3.5 M Euros.

The domain of Engineering Secure Software Services covers a collection of engineering activities that aim for the creation of software services —i.e. ICT services delivered through the deployment of software systems— that are both behaviorally correct (typically guided by software engineering principles) as well as secure (typically guided by security engineering principles). The specific engineering activities range from requirements engineering and analysis, over the creation of architectures, high-level and detailed design into implementation through the reuse and composition of existing artifacts, as well as through the programming of new entities, typically components and services.

The approach of engineering secure software services is based on the principle of addressing security issues from the very beginning in system design and analysis, thus contributing to reduce system and service vulnerabilities, improve the necessary assurance level, thereby considering risk and cost issues during development in order to prioritize investments.

IMDEA Software leads the researcher mobility program within the consortium. This program is a mechanism that supports the integration of activities across the various sites: it brings together researchers working on related topics; it drives knowledge exchange and knowledge generation through union and diversity; and, finally, it increases the capability of joint cooperation among researchers. IMDEA Software also plays a prominent role in three research workpackages: secure service architectures and design; programming environments for secure and composable services; and security assurance for services.
DESAFIOS-10
High-Quality, Reliable, Distributed, and Secure Software Development

Funding: Spanish Ministry of Science and Innovation
Duration: 2010-2013
Principal Investigator: Prof. Gilles Barthe

The overall goal of the DESAFIOS-10 is to contribute both foundations and technologies helpful in the development of software systems with certified quality and reliability, typically based on formal methods and declarative programming. The consortium involves groups from three different Institutions (Universidad Complutense de Madrid, Universidad Politécnica de Madrid, and IMDEA Software).

This project arises as a natural evolution of previous coordinated project DESAFIOS, involving only the research groups from the Universidad Complutense de Madrid and the Universidad Politécnica de Madrid. However, DESAFIOS-10 emphasizes the security and reliability aspects of this research, which is precisely the workpackage lead by IMDEA Software.

PROMETIDOS
Methods for Rigorous Software Development

Funding: Regional Government of Madrid
Duration: 2010-2013
Principal Investigator: Prof. Gilles Barthe

PROMETIDOS-CM research program is focused in four main areas: declarative programming, to develop the next generation of languages for services; specification and validation, to provide a solid foundation for the description and analysis of services; reliability and security, to guarantee robust solutions from start to end; and efficiency, to optimize quality of service with respect to performance. A common goal for all these research lines is the development of tools that will rigorously support their scientific results and that could be eventually transferred to industry.

PROMETIDOS-CM is a consortium involving groups from Universidad Complutense de Madrid, Universidad Politécnica de Madrid, and the IMDEA Software Institute, which is the project coordinator.
5.2. Projects with Associated Groups

Part of the research of the Institute is performed in collaboration with research groups at associated institutions. This is exemplified by the existence of research projects led by these institutions but in which IMDEA personnel take part (and the resulting joint publications and results). We provide a summary list of the most relevant such projects which were active during year 2010.

**PARAN-10**

Parameterized Verification of Computing Systems

Funding: Spanish Ministry of Science and Innovation  
Duration: 2010-2012  
Principal Investigator: Pierre Ganty

This project aims at developing novel techniques for production, verification and certification of computing systems where parameters play an essential role. Parameters either at the level of the system specification or at the level of the verification technique make it possible to address scalability and undecidability issues. However, specification and verification in the presence of parameters are highly non-trivial, and pose problems for automated verification methods (such as model checking) as well as interactive approaches to computing systems verification (such as theorem-proving), both of which are relevant in practice.

The project is organized along three research lines: model-checking of parametrized systems, parametric model-checking, and programming languages and logics for parametrization. In these three lines the project aims at making fundamental contributions to advance the state of the art as well as develop prototype implementations in order to explore and demonstrate the practical relevance of the proposed approaches.
This initiative explores directions and techniques for making automated reasoning (including analysis and synthesis) applicable to a wider range of problems, as well as making them easier to use by researchers, software developers, hardware designers, and information system users and developers. It includes participants from over 20 countries. A selection of the topics of interest is:

- **Standardization of expressive languages**: Definitions of formats to represent systems, formulas, proofs, counterexamples. A framework to specify translations between specification languages, as well as benchmarks and competitions for automated reasoning, verification, analysis, and synthesis.

- **Decision procedures**: Creation of decision procedures for new classes of constraints, including implementation of SAT and SMT and their certification. This will need the encoding of synthesis and analysis problems into SMT. We will also tackle the encoding of description logics (widely used in the Semantic Web) and the problem of scalable reasoning about knowledge bases.

- **Transition system analysis**: One key of study is the abstraction-based approaches and refinement for verification of infinite-state systems. The application of constraint-based program analysis will also be analyzed, as well as data-flow analysis for complex domains. The application of TSA to programming languages and bytecodes will be explored by extracting transition systems from them.

- **High-level synthesis**: The project will devise new algorithms for synthesis from high-level specifications, and decision procedures will be extended to perform synthesis tasks. A relevant point to explore will the the connection between invariant generation and code synthesis.
MTECTEST

New testing techniques for on-board software

Funding: Regional Government of Madrid
Duration: 2011 (awarded in 2010)
Principal Investigator: César Sánchez

This project will explore several techniques of software testing geared towards embedded systems. These techniques are being selected and tried in collaboration with DEIMOS Space, which participates in ESA projects focusing on software validation and verification. These techniques try to overcome practical limitations of existing approaches to verification, which may be too formal in some cases. They will work directly on executing programs and try to reach a level of accuracy in the tests, control of scenarios, and automation of the verification of the results higher than usual. An additional goal of this project is to study the effectiveness of these techniques when taking into account actual constraints of actual projects, such as development environments and testing frameworks.

NUSA

Numeric and Symbolic Abstractions for Software Model Checking

Funding: The Danish Council for Independent Research - Natural Sciences
Duration: 2011-2013
Principal Investigator: John Gallagher

Abstract interpretation and model checking are two approaches to verifying or deriving properties of software and hardware systems. While model checking is applied to finite-state systems (typically hardware), abstract interpretation is usually aimed at infinite-state software systems. Indeed, the very notion of verification by abstraction starts from the assumption that the system under consideration is infinite or very large. Both abstract interpretation and model checking are the subject of major research efforts, both in academic and industrial laboratories, since they hold out the promise of an automatic, push-button approach to obtaining guarantees of system behaviour. This proposal lies in the intersection of abstract interpretation and model checking. The main question for investigation in this project is how the framework and accumulated experience of abstract interpretation can be applied to model checking infinite state systems - in short, to define abstract model checking methods that exploit the generality and power of the framework of abstract interpretation.
5.4. Recently Finished Projects

**MOBIUS**

*Mobility, Ubiquity and Security*

*Enabling proof-carrying code for Java on mobile devices*

**Funding:** European Union, FET Global Computing Proactive Initiative- 6th Framework Program

**Duration:** 2005-2009

**Scientific Coordinator:** Prof. Gilles Barthe

Mobius is a European Integrated Project developing novel technologies for trustworthy global computing, using proof-carrying code to give users independent guarantees of the safety and security of Java applications for their mobile phones and PDAs. Prof. Gilles Barthe was the project scientific coordinator and, from 2008 on, the IMDEA Software Institute performed the administrative project management as the project coordinator. Mobius involved 17 partners, including 3 companies (namely, France Telecom, SAP AG Germany, and Trusted Labs), from 10 countries. The budget for the project was approximately 8 M Euros.

Global computing means that applications today may run anywhere, with data and code moving freely between servers, PCs and other devices: this kind of mobility over the ubiquitous internet magnifies the challenge of making sure that such software runs safely and reliably. In this context, the Mobius project focuses on securing applications downloaded to the Java MIDP platform: globally deployed across a host of phones, this is the common runtime environment for a myriad mobile applications.

Techniques of static analysis make it possible to check program behavior by analyzing source code before it ever executes. But mobile code means that this assurance must somehow travel with the application to reach the user. Conventional digital signatures use cryptography to identify who supplied a program; the breakthrough of proof-carrying code is to give mathematical proofs that guarantee the security of the code itself. We can strengthen digital signatures with digital evidence.

Key features of the Mobius security architecture are:

- Innovative trust management, with digital evidence of program behavior that can be independently checked by users or any third party.
- Static enforcement, checking code before it starts; adaptable to manage a range of user security concerns, and configurable to match the real-world mix of mobile platforms.
- Modularity, allowing developers to build up trusted applications from trusted components.
The IMDEA Software Institute developed key innovative technologies for mobile code security, including the design and implementation of efficient and automated methods for the enforcement of resource control and information flow policies, the development of advanced compilation infrastructures that support the automatic generation of digital evidence, and the design and implementation of highly reliable infrastructures to verify digital evidence.

**EzWeb**

**Funding:** Spanish Ministry of Industry, Tourism and Trade - Avanza2 Plan  
**Duration:** 2007-2009  
**Principal Investigator:** Prof. Manuel Hermenegildo

EzWeb is a collaborative project funded by MITyC, within the framework of The National Plan for Scientific Research, Development and Technological Innovation 2008-2011. The project is based on the development of key technologies to be employed in building the front end layer of a new-generation, Service-Oriented Architecture (SOA) that supports the following criteria:

- End-users must feel fully empowered. They must be able to self-serve from a wide range of available resources, providing access to content and application services, in order to set up their own personalized operating environment in a highly flexible and dynamic way (“Do it yourself”, IKEA philosophy).

- Active participation of users has to be enabled, allowing them to create resources as well as share and exchange both knowledge and resources with others and learn together, thus accelerating the way innovations and improvements in productivity are incorporated.

- Interaction must be adapted and relevant to context, giving the term "context" the widest possible meaning, in a way that comprises both user context (knowledge, profile, preferences, language, information about social networks the user belongs to, etc.) and delivery context (static and dynamic characteristics of the device used for access, geographical and time location, connection bandwidth, etc.). Dynamic context variability and user mobility must also be taken into consideration.

IMDEA Software has contributed to the EzWeb project providing a formal semantics for the main components of the EzWeb platform, thanks to which its software can be in principle checked for correctness and its behavior can be (automatically) reasoned about.
ES_PASS
Embedded Software Product-based Assurance

Funding: ITEA2 cluster of EUREKA Program; MITyC – PROFIT and AVANZA2
Duration: 2007-2009
Principal Investigator: Profs. Manuel Hermenegildo and Pedro López-García

The research goal of ES_PASS is to improve and integrate state-of-the-art software verification techniques based on static analysis in existing industrial engineering processes in the domain of critical embedded systems.

Technology and tools for verification of critical properties in software are provided by the Technology Providers to the Industrial Domains (in particular, to the aerospace, automotive and railway transportation domains). With the benefit of the experience in the development of critical systems, industry sectors bring requirements, evaluate the tools, and assess their impacts on engineering processes. Technology providers improve the industrial-strength of their technology and improve dissemination.

The technology providers within the ES_PASS consortium are: AbsInt Angewandte Informatik GmbH, CEA-LIST, École Normale Supérieure, EADS CCR, CNRS FèRIA federation, Fraunhofer FIRST, Compiler Design Lab, Technical University of Munich, Tel-Aviv University, Saarland University, and Universidad Politécnica de Madrid (in part through IMDEA Software personnel). The industrial end-users in the ES_PASS project are: Airbus France, CS Systèmes d’Information and Thales Avionics (for the aeronautics domain); Daimler AG, PSA Peugeot Citroen and Siemens VDO Automotive (for the automotive domain); Astrium SAS and GTD Barcelona (for the aerospace domain); and, ALCATEL TSD and IFB Berlin (for the railway transportation domain).

**High Integrity Software: When Software Has To Fly**

Some software cannot fail, in some important real world applications. This software is called high integrity software and must be trusted to work dependably in some critical function. Failure in these programs may have catastrophic results in terms of lives or high economic cost. For example, failure in a program used by air traffic controllers could lead to fatal accidents; a failure in a medical system providing treatment could lead to irreversible damage; failures in parts of automobile systems such as brake controllers, apart from being potentially dangerous, could lead to massive and costly recalls. In fact, all of these scenarios have occurred already.

Software engineering practices balance between the cost (and time) to complete a project, and the quality of the outcome. The rapidly growing demand for new, larger software projects with more complex functionality has increased industry demand for software developers. In turn, this need has motivated a trend towards reducing the training necessary for software engineers and developers to enter the job market. However, at the same time, the quality of the software produced has become more and more difficult to guarantee. The issue with software quality is witnessed by the fact that the dominant factor of the overall cost of current industrial software projects is testing, and not building the product itself. Even in non-critical projects testing dominates more than 90% of the total cost.

The quality and reliability requirements of high integrity software justifies the investment in scientific undertakings to create a body of knowledge about how to build more reliable software. These new techniques intend to provide better guarantees of quality, at the price of using more sophisticated methods and tools by properly trained software engineers. Moreover, in the long run these methods could also lead to more productive software processes.

Researchers from the IMDEA Software Institute have developed – and continue to develop – cutting-edge technologies for high-integrity software following two different approaches. First, a fundamental attempt to create the basic science that can be used to craft the high-integrity software of the future. These techniques are designed to provide the best guarantee of adherence to intended behavior. Completed and ongoing
projects include the use of high-order theorem proving to verify programs and libraries, static analysis for functional and non-functional properties of real-time and embedded systems, and temporal verification of reactive systems, in particular concurrent data types. At the same time, the IMDEA Software Institute has developed novel lightweight and applicable techniques that can be directly incorporated to improve existing software practices: advanced visualization of heap-manipulating programs, debugging of production system programs, and online monitoring of embedded reactive programs based on runtime verification.

The IMDEA Software Institute is collaborating with the leading aerospace company Deimos, located in the area of Madrid, on the technology transfer of these techniques. This continuing effort started with the rigorous and systematic development of software for satellite image processing. The aim of this project is to develop the tools to interactively synthesize provably correct software, based on a formal approach to software families, applied to image processing. Using these tools software engineers can develop very efficient parallel software that can be verified with independent tools. Moreover, different projects can experience dramatic cost gains by the increase in the level of reuse by the use of software families.

Figure 7.1: Satellites have to be autonomous up to a certain degree. The programs running in their computers continuously monitor for deviations from their scheduled trajectories and take the appropriate decisions to correct them.
Language-based Security: Building Trustworthy Software for the Interconnected World

Current computing environments and infrastructures are increasingly heterogeneous and dynamically changing. Executable mobile programs are everywhere: web pages, email, plug-and-play extensions, JavaScript, on-line games, Word and PowerPoint documents and attachments, electronic banking... Software is constantly being updated and downloaded over the Internet, sometimes without our knowledge or consent. Yet, today’s security architectures provide poor protection from faulty software, and even less from malicious software. These security architectures were developed at the time when software was managed and updated infrequently by an experienced administrator, we trusted the (few) programs we ran, physical access to the systems was required to cause any damage to the data, and crashes and outages did not cost billions. As none of these conditions is valid anymore, our information systems have become increasingly susceptible to attacks with potentially devastating consequences.

To accommodate for the new trends in software use and deployment, the IMDEA Software Institute is working on developing new security architectures that are well suited for networked computing systems built from diverse and extensible components. We leverage techniques from programming language and logic design, to address the following issues.

- As mobile programs move on the network, it is important for them to gain trust of the new host by presenting verifiable evidence that they conform with the host’s security policy. One of our research concerns is developing languages and logics in which such verifiable evidence can be constructed in the form of a rigorous mathematical proof. Another concern is helping the code producers to construct such mathematical proofs as automatically as possible, without requiring a prohibitive investment of time and resources.

- Various hosts may have various security policies. For example, mobile phones may allow downloading games from certain web-sites, but not from certain others. On the other hand, a hospital information system will probably never concern itself with downloading games, but will focus on ensuring that confidential patient data is not leaked to unauthorized personnel, or to the general public. A research concern here is, again, in designing languages and logics in which a wide variety of security policies can be specified.
One of the general directions that the IMDEA Software Institute is pursuing in our general research in programming languages, and towards the goal of mobile software design in particular, is the development of expressive type systems that integrate programming, specification of security policies, and proving that programs respect the policies, into one and the same language. Such an integration is highly desirable for several reasons. First, programs written in a combined language are equipped with the (condensed) proofs of their security. The code consumer can convince themselves of the code security by inspecting this proof – usually a rather simple operation. Second, combining programs and specification leads to better maintainability and reuse of programs and proofs. For example, if a program is shown secure with respect to the specification of some library, it can readily be linked against any version of that library, without requiring potentially expensive refactoring. Third, programming facilities can be brought to use in the production of specifications and proofs. For example, one can implement decision procedures within the system itself, and use them to automate the parts or the whole of the proof development. This makes the proofs themselves relatively short and manageable, instead of being a serious burden on the programmer or the verifier that they are in today’s state-of-the-art verification systems.

We have also shown that such mathematics-based security infrastructure can be put to use in practice. For example, in the Mobius project, jointly with France Telecom and INRIA, we have shown the feasibility of on-device checking of mathematical proofs, using dedicated checkers developed and extracted from rigorous mathematical formalizations in the proof assistant Coq.
Towards “Greener” Software: Verifying & Controlling Computing Resource Consumption

The conventional understanding of software correctness is absence of errors or bugs with respect to a functional or behavioral specification, i.e., with respect to what the program is supposed to compute or do. However, in an increasing number of computer applications the world outside the computer plays an essential role. For example, embedded systems must control and react to the environment, which in turn establishes constraints about the system’s behavior like resource usage and reaction times. This makes it necessary to extend the criteria of correctness with new kinds of aspects including upper and lower bounds on execution time, usage of memory, energy consumed, or user defined resources.

The challenge is to extend debugging and verification techniques and tools to deal with resource usage properties, allowing automated performance debugging and certification of programs. This requires developing novel analysis techniques for resources and also improving more conventional analyses for data shapes, data sizes, metrics, aliasing and sharing, etc. Another novel aspect of resource verification is that static checking must generate answers that go beyond the classical outcomes (true/false/unknown). To be useful, these answers must often include conditions under which these classical outcomes are obtained, including input data size or value ranges. For example, it may be possible to say that the outcome is true if the input data size is in a given range.

Resource usage optimization has also become a leading design constraint in current computing devices. As simple examples, in office environments computers and monitors
account for the highest energy consumption after lighting, and many mobile devices are limited by battery capacity.

The objective is to develop tools that facilitate the development of “greener” devices, i.e., devices that make a certifiably more efficient use of their available resources. Resource-aware and resource usage-certified programs will allow improving existing devices and applications (like mobile phones and on-board satellite software), enables new uses (like portable medical devices), and reduces the environmental impact of the devices they control.

Researchers from the IMDEA Software Institute are developing state-of-the-art techniques and tools to craft and verify resource-aware software. The pioneering CiaoPP system provides a general framework for computing with high precision the resources consumed by a given piece of software and for debugging/certifying such consumption with respect to specifications. This includes classical concerns like execution time, memory, or disk space as well as other user-defined or platform-dependent resources like energy, network accesses, or opened files. This system has also pioneered analyses whose results are parametric on the values and sizes of inputs, and not only for closed programs. Consequently, it can be used for compositional resource analysis, including libraries and open systems. The platform is highly adaptable to different languages, hardware, and resources because it is built around a customizable static analyzer with a versatile and clear assertion language. Furthermore, within the ES_PASS project IMDEA scientists have shown the applicability of these techniques to automatically determining the resource usage of aerospace software and other embedded industrial applications. This has included demonstrations to the project's industrial partners and tests on concrete code examples extracted from their application codes.

Researchers from the IMDEA Software Institute are also pioneering the development of combined hardware/software techniques for increasing the reliability and reducing the power needs of portable medical devices. These applications demand high reliability and a stringent use of resources, which cannot be met with state-of-the-art hardware design and/or conventional software techniques. In this project, IMDEA scientists are using software resource control and parallelization techniques together with specialized hardware which are together aimed at meeting reaction times while decreasing hardware clock frequency in order to meet the power, temperature, and reliability demands. This will enable the design of smaller, more portable, more durable, and more reliable medical devices.
Parallelism for the Masses: Towards Cost-effective Exploitation of Ubiquitous Parallelism

A radical change in computer system architecture is currently taking place. Mainstream microprocessor manufacturers have switched from a monolithic model with a single CPU to a decentralized model with multiple CPU cores in the same chip. Multicore processing units with more than 100 computing units are already in production. The reason for this paradigm shift is that intrinsic physical limitations prevent increasing CPU clock frequencies much further. Since new applications always pose increasing performance requirements, parallelism is now being widely used to meet these demands. This paradigm shift is affecting a wide spectrum of computing devices, including laptops, medical devices, smart phones, future automotive and avionics technology, or home entertainment.

However, current approaches to developing software for these new platforms make poor use of the performance offered by their parallelism. The software industry is in dire need for new approaches for building and verifying multicore software. The problem is that programming highly parallel systems is a very challenging task. One approach consists in taking programs written in traditional, imperative languages and parallelizing them using automated techniques. Although this approach has shown some promises for...
modest amounts of parallelism the benefits quickly degrade when more processors are added, due to the excessively serial nature of these programming paradigms. The scientific community is thus seeking novel programming paradigms that allow a much higher degree of exploitation of parallelism in a cost-effective way. Another approach consists in writing parallel programs manually but the primitives currently available are in general too low-level and the process too error prone.

Scientists at the IMDEA Software Institute are developing two of the more promising approaches to meet these challenges. The first one consists in designing and using more declarative programming languages and developing tools for their automated and user-assisted parallelization. These tools tackle the identification of independent tasks as well as the complex problem of controlling that the tasks generated are of sufficient size, through a combination of static and dynamic resource and data size analyses.

The second is to use programming based on events and tasks which are respectively triggered and completed in no particular order. This approach allows a program to exploit massive parallelism. The challenges stem from the fact that there is no guarantee on the ordering in which the instructions will be executed. Even worse, the underlying architecture provides no guarantee regarding on which CPU core the instructions are going to be executed. For those reasons, parallelism greatly complicates the assessment of correctness of these software systems. In this setting, testing, which is the most used software engineering technique for validating software reliability, provides very little confidence. The problem stems from the limited coverage of testing with respect to the very large spectrum of system's behaviors. By defining and then querying a mathematical model of the system's behavior one can acquire a level of confidence in the system which is not possible with testing. The definition and querying (fully automatically or human-assisted) of those models is another grand challenge that is being addressed at the IMDEA Software Institute.
